PAPER PRESENTATION • NEW-IDEA PROPOSAL

[Specific title of your proposed research idea]

Student(s): [Your name(s)] **Presentation:** [Date]

Based on: [Paper title, authors, and year]

Propose one testable extension of the presented paper, not just a summary. Replace the bracketed prompts. Keep one page, including references, with 11-point text and the existing margins. Suggested length: 420–520 words.

1. Background and motivation

50–60 words

[Explain the problem the paper addresses, why it matters, and the main contribution that your idea builds on. Give enough context for a classmate who has not read the paper. Cite the relevant method or result; do not summarize every section.]

2. Gap and research question

50–60 words

[Identify one limitation, missing comparison, or untested assumption. Point to a specific section, figure, experiment, or equation when possible. Distinguish the paper's stated limitation from your own observation. End with one focused question: "Can [specific change] improve [outcome] under [conditions]?" Explain why answering this question is worthwhile.]

3. Proposed idea and novelty

110–140 words

[Describe exactly what you will change and what stays the same. Explain the inputs, the main steps, and the expected output. Include a short concrete example or a small equation only if it makes the idea clearer. Explain why the change might address the gap. State how it differs from the original paper; do not present an existing paper component as your new contribution. A modest, well-defined extension is sufficient. Check related work before claiming broader novelty.]

4. Evaluation plan

120–140 words

[Name the task, dataset or test cases, model, and a feasible pilot size. Compare with the original method and at least one simple alternative. Identify the main metric and a concrete success criterion. State which resources and settings must be matched for a fair comparison. Include one ablation that removes your proposed component. Keep development and test examples separate. Explain how you will handle variability, cost, failures, and an inconclusive result. For a theoretical idea, specify the claim, assumptions, and proof or counterexample strategy instead.]

5. Expected outcomes and risks

50–70 words

[State your hypothesis, not invented results. Explain where the idea should help, one plausible reason it could fail, and a fallback or diagnostic test. Say what a negative result would teach us. Make clear which numerical values are goals rather than observed improvements.]

6. Feasibility and deliverables

40–50 words

[Give a short schedule, required data or computing resources, and the smallest version you could realistically test. Name the deliverables, such as a prototype, comparison plot, proof sketch, or error analysis. Separate the essential pilot from optional extensions.]
